CONVERSION FACTORS AND ABBREVIATIONS

<i>Multiply</i>	<i>By</i>	<i>To obtain</i>
foot (ft)	0.3048	meter
inch (in.)	25.40	millimeter
mile (mi)	1.609	kilometer
square mile (mi^2)	2.590	square kilometer

Degrees Fahrenheit ($^{\circ}\text{F}$) can be converted to degrees Celsius ($^{\circ}\text{C}$) by using the formula $^{\circ}\text{C} = 0.5556 (^{\circ}\text{F} - 32)$.

SEA LEVEL

In this report, "sea level" refers to the National Geodetic Vertical Datum of 1929 (NGVD of 1929, formerly called "Sea-Level Datum of 1929"), which is derived from a general adjustment of the first-order leveling networks of both the United States and Canada.

Data on Ground-Water Quality in the Winnemucca
District of the U.S. Bureau of Land Management,
Northwestern Nevada, 1934-87

By Kerry T. Garcia and Judy M. Jacoboni

ABSTRACT

This report is a compilation of data on the quality of ground water in the Winnemucca District of the U.S. Bureau of Land Management. It includes data on 591 samples collected from 530 wells and springs from 1934 to 1987.

The water-quality data in this report include specific conductance, pH, water temperature, color, turbidity, hardness, cations (calcium, magnesium, sodium, potassium), alkalinity, anions (carbonate, bicarbonate, sulfate, chloride, fluoride), silica, dissolved solids, nitrate, ammonia, and phosphorus. In addition, some analyses include the trace constituents aluminum, antimony, arsenic, barium, beryllium, bismuth, boron, cadmium, chromium, cobalt, copper, iron, lead, lithium, manganese, mercury, molybdenum, nickel, selenium, silver, strontium, tin, vanadium, and zinc. Data for hydroxide, sulfide, bromide, iodide, nitrite, cesium, gallium, germanium, rubidium, titanium, zirconium, tritium, deuterium, oxygen-18, carbon-13, and the gases argon, carbon dioxide, ethane, hydrogen, methane, and oxygen for a limited number of sites are also included. Limited data for radionuclides, stable isotopes, and organics also are listed. Some samples exceeded primary drinking water standards for fluoride, trace constituents, and nitrates.

INTRODUCTION

The Winnemucca District of the U.S. Bureau of Land Management (BLM) encompasses about 13,000 square miles in northwestern Nevada (figure 1). Several small streams, including the Humboldt, Little Humboldt, Kings, and Quinn Rivers, and many springs and wells are in the District.

The BLM is responsible for the management of large tracts of public land in Nevada. Baseline data on the quality of ground water on those lands are necessary for development and execution of plans for land management and watershed protection, and for development and protection of domestic and livestock water supplies. Because of this need, the U.S. Geological Survey (USGS), in cooperation with the BLM, began a two-phase study within the Winnemucca District.

Purpose and Scope

This report presents the results of the first phase of the study. The purpose of the first phase was to compile a data base of the quality of the ground-water resources from existing information about water quality in the Winnemucca District. The scope of the work included an inventory and compilation of existing information and publication of the data. Previously published reports were the source of much of the water-quality data.

Phase two, as planned, will study the adequacy of data that were compiled and inventoried in phase one to address the suitability of the ground water for beneficial uses. Phase two also may include initiation of a monitoring program designed to meet shortcomings in the present data base.

Acknowledgments

The authors are grateful for the assistance provided by personnel of the BLM and the Nevada Department of Human Resources, Bureau of Consumer Health Protection Service (NBCHPS). Some of the water-quality data were provided by NBCHPS.

Previous Studies Related to Hydrology

Several hydrologic studies of selected areas in and around the Winnemucca District have been made. Most of the studies were reconnaissance investigations; they include brief descriptions of the geology, hydrology, and water quality. The reports are as follows:

GEOGRAPHIC AND HYDROLOGIC SETTING

The Winnemucca District in northwestern Nevada includes part or all of 47 hydrographic areas (Rush, 1968) in Nevada (figure 2). The District lies almost entirely within the Great Basin, and is characterized by a series of generally north-south-trending mountains and valleys. The mountains form the topographic and drainage divides between the hydrographic areas and can impede ground-water movement between adjacent valleys. Much of the Winnemucca District is high desert, with altitudes ranging from about 4,000 to 9,800 feet above sea level.

The Humboldt River is the major stream in the area, flowing through and terminating in the Winnemucca District (figure 1). The stream begins in eastern Nevada and flows southwestward and westward before entering the eastern part of the study area. The stream then flows northwestward for about 50 miles before turning southwestward again and flowing into Rye Patch Reservoir. The natural terminus of the stream is the Humboldt Sink, south of Lovelock.

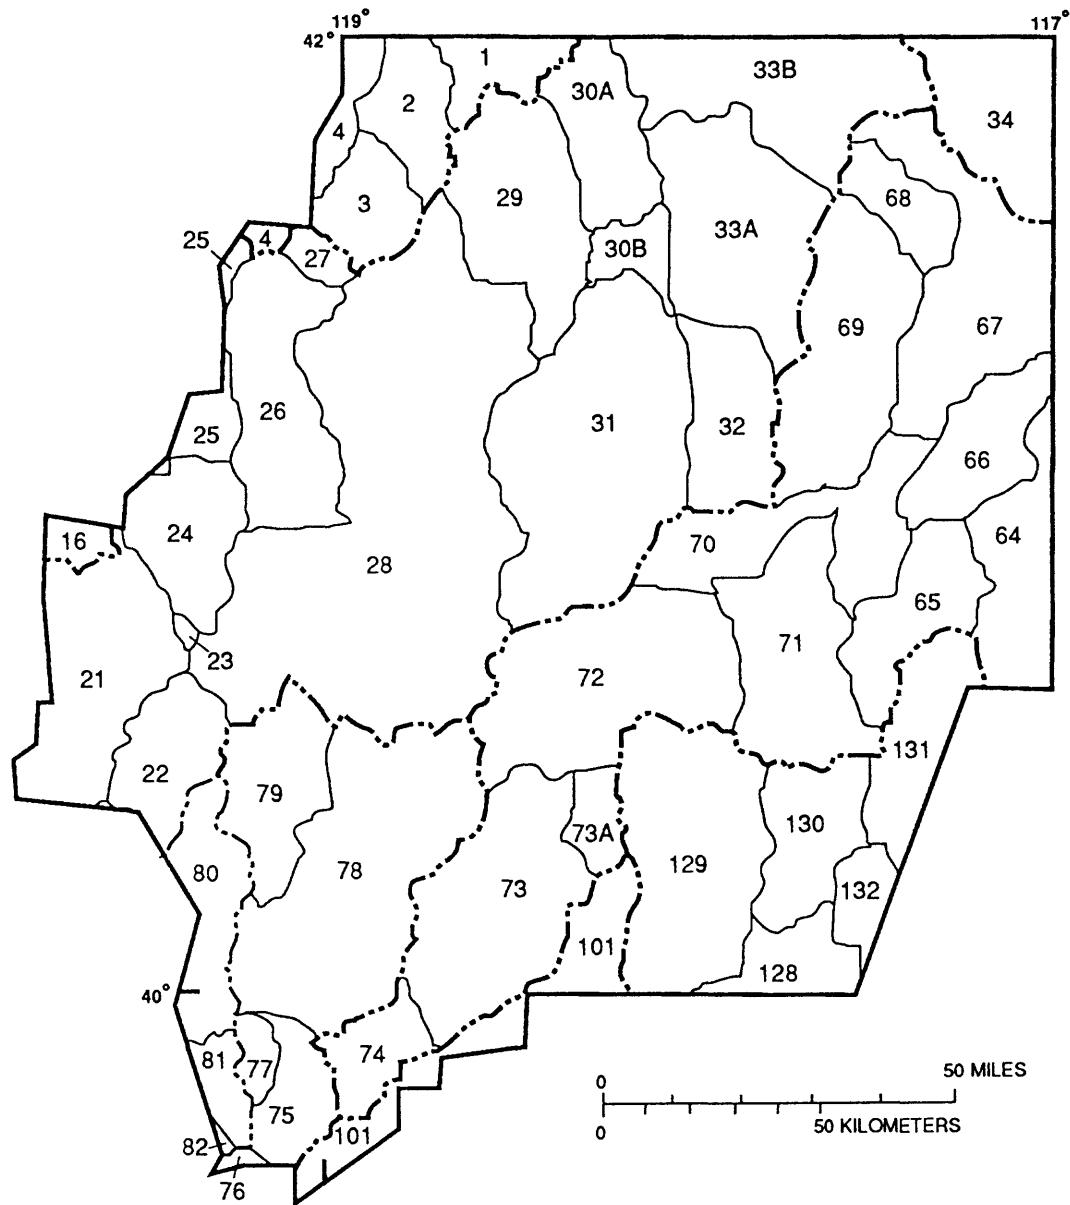

Water released from Rye Patch Reservoir is used primarily for irrigation in the Lovelock area. The water that flows into the Humboldt Sink is mostly excess irrigation and wastewater from the Lovelock area.

The Little Humboldt River and its tributaries lie mostly in the Winnemucca District. Flow from this stream is diverted and used for irrigation in Paradise Valley. Excess irrigation and wastewater that does not evaporate or percolate, and is not transpired, flows into the Humboldt River near Winnemucca.

Kings River is a small stream in the northern part of the District that is a tributary of the Quinn River. Several other small streams lie within the District and generally terminate on the valley floors.

The Winnemucca District encompasses all or parts of Churchill, Humboldt, Lyon, Pershing, and Washoe Counties, with Humboldt (population, about 12,000) and Pershing (population, about 4,400) Counties comprising most of the District. The Winnemucca District has two major population centers, Winnemucca (population, about 6,000) and Lovelock (population, about 2,200), which provide most of the services required by people in the District (J.P. Comeaux, Nevada Department of Taxation, written commun., 1987). Smaller rural communities and ranches also are in the area.

The Sierra Nevada range along the western Nevada border and air masses moving eastward from the Pacific Ocean are important factors that control the climate in the study area. As the air masses move over the Sierra Nevada, the air cools and much of the moisture condenses and precipitates in the mountains. Consequently, the project area has a subhumid climate in the mountains and an arid to semiarid climate in the valleys.

FIGURE 2.--Continued.

Average annual precipitation (National Climatic Center, 1987) at three weather stations in the study area (figure 1) is:

Station name	Altitude (feet above sea level)	Average annual precipitation (inches)
Lovelock	3,975	5.5
Paradise Valley	4,675	9.2
Winnemucca	4,297	7.9

Generally, most of the precipitation falls in the winter as snow. In the summer, precipitation is generally rain from thunderstorms.

Air temperature in the study area can fluctuate as much as 50 °F in a 24-hour period during the summer and as much as 30 °F in the winter. The mean annual air temperature at Winnemucca is about 49 °F. The average monthly temperature in January is about 30 °F, whereas in July it is about 72 °F. However, temperatures as low as -36 °F and as high as 108 °F have been recorded in Winnemucca.

METHODS USED IN THE STUDY

Data on ground-water quality in the Winnemucca District were extracted from a statewide data base maintained by the USGS. The data base included information on 591 water samples collected from 530 wells and springs from 1934 to 1987. Most of the samples reported in the data base were analyzed for specific conductance, pH, temperature, color, turbidity, hardness, cations (calcium, magnesium, sodium, and potassium), alkalinity, anions (carbonate, bicarbonate, sulfate,¹ chloride, and fluoride), silica, dissolved solids, nitrate, ammonia, and phosphorus. In addition, about 30 percent of the samples were analyzed for at least some of the following trace constituents: aluminum, antimony, arsenic, barium, beryllium, bismuth, boron, cadmium, chromium, cobalt, copper, iron, lead, lithium, manganese, mercury, molybdenum, nickel, selenium, silver, strontium, tin, vanadium, and zinc. Data for hydroxide, sulfide, bromide, iodide, nitrite, cesium, gallium, germanium, rubidium, titanium, zirconium, tritium, deuterium, oxygen-18, carbon-13, and the gases argon, carbon dioxide, ethane, hydrogen, methane, and oxygen for a limited number of sites are also included. Limited data for radionuclides, stable isotopes, and organics also are listed.

¹ Ammonia data are the result of an analytical procedure that determines the combined concentration of the ammonium ion (NH_4^+) plus un-ionized ammonia (NH_3). In most waters having a pH of less than about 8.5, the concentration of ammonium exceeds that of ammonia.

Verification of site locations and analytical results was not within the scope of this project. However, as a check on the accuracy of the chemical analyses, the electrical balance between the cations and anions was compared. If the difference between the sum of the major cations and the sum of the major anions, expressed in milliequivalents per liter, exceeded 10 percent, the analysis was considered inaccurate and was excluded from the data compilation. When the electrical imbalance was small, the accuracy of the analytical results was considered acceptable. The imbalance calculation is:

$$\text{Imbalance (in percent)} = \frac{(\text{cations} - \text{anions})}{(\text{cations} + \text{anions})} \times 100$$

This check, which can be made only if all major ions have been analyzed and reported, could be made on about 40 percent of the analyses. Of those, 18 out of 228 had an imbalance that exceeded 10 percent and were eliminated from the data compilation.

Some of the reconnaissance reports (p. 4) include data that had not been stored in the water-quality data base. For the sites in these reports with water-quality data, well and spring locations were retrieved from the USGS site file, the location information was matched with the sites in these reports, and the data were then entered into the data base.

A few analyses from the NBCHPS were also entered into the water-quality data base if a site location could be matched with the analysis.

The analytical methods in use, their accuracy, precision, and detection limits, and the laboratory performing the analyses must be considered when interpreting water-quality data from extended time periods. Differences in sampling and sample handling must also be taken into account. Changes in sampling procedures and analytical techniques can have a significant effect on water-quality data. Geological Survey Water-Supply Paper 1454 and the first, second, and third editions of Book 5, Chapter A1, Techniques of Water-Resources Investigations of the United States Geological Survey can be consulted for information about USGS methods from 1960 to the present.

WATER-QUALITY CRITERIA FOR BENEFICIAL USE

Domestic Use

With modern technology and treatment, almost any ground water can be treated to meet drinking-water standards; however, the costs involved can be prohibitive. To be suitable for domestic use, ground water is generally expected to meet drinking-water standards with little or no treatment. Constituents in ground water may exceed a standard without injury to health; the concentration and duration depends on the nature of the constituent (National Academy of Sciences and National Academy of Engineering, 1973, p. 51).

Drinking-water standards for many constituents have been adopted by the State of Nevada. Those standards--as well as Federal standards--and the sources and significance of selected water-quality constituents, are listed in table 1. Nevada public-supply standards do not apply to individual private water supplies; however, they are used as recommended maximum concentrations (Darrell Rasner, NBCHPS, oral commun., 1986). Sites in the Winnemucca District where primary drinking-water standards were exceeded are listed in table 2 and shown in figures 3-5.

Agricultural Use

High concentrations of some constituents are toxic to animals or may accumulate in their tissues and body fluids, making them unsafe for human consumption (National Academy of Sciences and National Academy of Engineering, 1973, p. 309). Concentrations of constituents that make a water undesirable for livestock depend on several variables, such as age, sex, species, physiological state, water intake, and diet of the animal; the oxidation state of the toxic constituents; and the temperature of the environment (National Academy of Sciences and National Academy of Engineering, p. 309).

The criteria generally used to determine if a water is suitable for irrigation are (1) dissolved solids concentration (salinity hazard), (2) proportion of sodium to calcium plus magnesium (alkali hazard), and (3) boron concentration (toxicity hazard). Specific conductance is an indication of the salinity hazard because of its relation to dissolved solids. Dissolved-solids concentration can be estimated by multiplying specific-conductance values by a factor generally ranging from 0.55 to 0.75 (Hem, 1985, p. 67).

The alkali hazard is related to specific conductance and the SAR (sodium adsorption ratio). SAR is defined as follows:

$$SAR = \frac{(Na)}{\sqrt{[(Ca) + (Mg)] / 2}}$$

where (Na), (Ca), and (Mg) are the concentrations of sodium, calcium, and magnesium, respectively, expressed in milliequivalents per liter (U.S. Salinity Laboratory Staff, 1954).

Table 3 lists the recommended concentrations for selected constituents in water for agricultural use; table 4 classifies selected plants as to their relative tolerance to boron; and table 7 (back of report) shows ranges in values for selected constituents and properties of water from wells and springs in the study area.

TABLE 1.--Background information on constituents and properties of water

[Modified from Thodua (1989, table 4). Abbreviations: EPA, U.S. Environmental Protection Agency; NAS-NAE, National Academy of Sciences and National Academy of Engineering; NBCHPS, Nevada Bureau of Consumer Health Protection Services (1980); mg/kg, milligrams per kilogram; mg/L, milligrams per liter; mrem, millirems; mL, milliliter; pCi/L, picocuries per liter; $^{\circ}\text{C}$, degrees Celsius; >, greater than; --, no data available]

Constituent or property	Source or cause of occurrence	Normal range of values in natural waters	Standards or criteria for water use ¹	Remarks
Principal Constituents and Properties				
Specific conductance	Capability of water to conduct electric current at specified temperature of 25 $^{\circ}\text{C}$. Presence of charged ionic species dissolved in water makes solution conductive, whereas pure liquid water (without dissolved ions) has very low electrical conductance. As ion concentrations increase, conductance of solution increases; therefore, specific conductance is indication of ion concentrations (Hem, 1985, p. 66).	Generally less than 1,000 microsiemens per centimeter at 25 $^{\circ}\text{C}$ for potable water (Hem, 1985, p. 67).	No enforceable standard.	Provides field estimate of ion concentration and quality control for associated laboratory analysis.
pH	A measure of acidity (pH value less than 7.0) or alkalinity (pH greater than 7.0) of water; is based on effective concentration (also called "activity") of dissolved hydrogen ions. Primary source of hydrogen ions in most natural ground-water systems is from reaction of water with carbon dioxide that is produced by soil microorganisms; this reaction forms dissolved bicarbonate and hydrogen ions (Hem, 1985, p. 61-63).	The pH of pure water at 25 $^{\circ}\text{C}$ is 7.00 (which is termed a neutral pH). Typical groundwater values range from about 6.0 to about 8.5 (Hem, 1985, p. 63-64).	Secondary standard: range of acceptable pH is from 6.5 to 8.5 (NBCHPS).	Toxicity of certain compounds (such as hydrogen cyanide or ammonia), solubility of metal compounds, and corrosiveness of water are affected by pH (EPA, 1976, p. 178-179). The pH is also a controlling factor in geochemical equilibrium.

TABLE 1.--Background information on constituents and properties of water--Continued

Constituent or property	Source or cause of occurrence	Normal range of values in natural waters	Standards or criteria ¹ for water use ¹	Remarks
Turbidity	Semiquantitative measure of light scattering due to suspended inorganic and organic particles, precipitates, colloids, and plankton. May be derived from soil erosion, algal blooms, industrial wastes, sewage, or chemical reactions such as oxidation of dissolved iron.	--	Secondary standard: 1 to 5 standard turbidity units, depending upon population served by water-supply system (NBCHPS).	Esthetically objectionable in drinking water.
Hydrogen sulfide (H_2S)	Found naturally in some hydrocarbon gas accumulations and in volcanic gases. Also can be found near paper mills and tanneries.	Most people can detect odor of hydrogen sulfide in water when concentration is few tenths of mg/L (Hem, 1985, p. 117).	Level of undissociated hydrogen sulfide assumed to be safe for aquatic organisms is 0.002 mg/L (NAS-NAE, 1973, p. 193).	Hydrogen sulfide is irritant; on chronic exposure, concentrations may produce conjunctivitis or pulmonary edema (Smith, 1980, p. 329).
Hardness (as $CaCO_3$)	Derived principally from dissolved calcium and magnesium.	Commonly 200 to 300 mg/L in carbonate ground water.	No enforceable standard.	Consumes soap and detergents before lather will form, resulting in soap curds depositing on sinks and bathtubs. Hard water forms scales in pipes, boilers, and water heaters. Water-hardness classification: 0-60 mg/L, soft; 61-120 mg/L, moderately hard; 121-180 mg/L, hard; more than 180 mg/L, very hard. Soft water is corrosive to metal pipes and fixtures.
Calcium (Ca) and magnesium (Mg)	Dissolved from rocks and soils, especially those containing limestone, dolomite, and gypsum.	Calcium: 1 to more than 1,000 mg/L. Magnesium: Normally much less than calcium and usually less than sodium (Hem, 1985, p. 89-100).	Secondary standards for magnesium: 125 mg/L unless alternative supply unavailable, then 150 mg/L (NBCHPS).	Impart hardness and scale-forming properties to water (see hardness). High concentrations unsuitable for laundries, steam plants, textile processing, dyeing, and electroplating. Small amounts desirable to prevent corrosion.

TABLE 1.--Background information on constituents and properties of water--Continued

Constituent or property	Source or cause of occurrence	Normal range of values in natural waters	Standards or criteria for water use ¹	Remarks
Sodium (Na) and potassium (K)	Dissolved from most rocks and soils. High concentrations may be found in natural brines, industrial waste, and sewage.	Sodium: Generally 1 to 1,000 mg/L. Potassium: Commonly 0.1 to 0.5 times sodium; generally less than 10 mg/L (Hem, 1985, p. 100-105).	No enforceable standard.	Concentrations greater than 50 mg/L may cause foaming in boilers. Combine with chloride to impart salty taste. Sodium may contribute to hypertension and cardiovascular diseases. Sodium may be objectionable in irrigation water at concentrations that depend on type of crop and soil.
SAR (Sodium-adsorption ratio)	Mathematical computation using calcium, magnesium, and sodium.	Less than about 5 mg/L.	None.	Used as gross measure of suitability of water for irrigation.
Bicarbonate (HCO ₃) and carbonate (CO ₃)	Dissolved from most rocks and soils by carbon dioxide reacting with carbonate minerals such as limestone and dolomite. Carbonate ion can exist only if the pH is 8.3 or more.	Bicarbonate: Generally less than 200 mg/L in surface water and 50 mg/L in ground water. Carbonate: Generally less than 10 mg/L (Hem, 1985, p. 105-109).	No enforceable standard.	Increases alkalinity and, usually, pH of water. In combination with calcium and magnesium, causes scales in pipes and, upon heating, may release corrosive carbon dioxide.
Sulfate (SO ₄)	Dissolved from rocks and soils containing gypsum and sulfide or sulfate minerals. Commonly associated with coal deposits, metallic ore deposits, and geothermal areas. May be derived from industrial wastes and atmospheric pollution.	Generally ranges from 1 to 1,000 mg/L (Hem, 1985, p. 116-117).	Secondary standards: 250 mg/L unless alternate supply unavailable, then 500 mg/L (NBCHPS).	Forms boiler scale in combination with calcium. Causes bitter taste when combined in high concentrations with other ions and may have laxative effects when ingested in higher concentrations than an individual is accustomed to. Combines with hydrogen ions in low-pH water to form sulfuric acid.
Chloride (Cl)	Dissolved in differing amounts from all rocks and soils. High concentrations may be derived from marine and desert evaporites and brines. Commonly present in sewage and industrial wastes. May be derived from salts used for control of ice on streets and highways.	Commonly less than 100 mg/L in potable water (Hem, 1985, p. 117-120).	Secondary standards: 250 mg/L unless alternate supply unavailable, then 400 mg/L (NBCHPS).	May contribute to corrosiveness of water. Imparts salty taste in concentrations as low as 100 mg/L. The chloride ion is very stable in ground water and is often used as a tracer of ground-water movement in aquifers.

TABLE 1.--Background information on constituents and properties of water--Continued

Constituent or property	Source or cause of occurrence	Normal range of values in natural waters	Standards or criteria for water use ¹	Remarks
Fluoride (F)	Dissolved in small amounts from most rocks and soils. Added to many public water supplies to inhibit tooth decay.	Commonly less than 1.0 mg/L in potable natural water (Hem, 1985, p. 120-123).	Primary standard, 4.0 mg/L; secondary standard, 2.0 mg/L (EPA, 1986).	Concentrations between 0.6 and 1.7 mg/L may have beneficial effects on the structure and resistance to decay of children's teeth. Concentrations in excess of 6.0 mg/L may cause mottling and disfigurement of teeth (NAS-NAE, 1973, p. 66).
Bromide (Br)	Similar in chemical behavior to chloride, but much less abundant (Hem, 1985, p. 146).	Normal range, 5-150 µg/L in precipitation; geothermal water may have >20 mg/L (Hem, 1985, p. 146).	None.	Gasoline additive, fumigants, fire-retardant agents (Hem, 1985, p. 46).
Iodide (I)	Not abundant, but widely distributed.	Rainwater, 1-3 µg/L; may be concentrated in some brines (Hem, 1985, p. 146).	None.	Silver iodide has been used for cloud seeding. Is essential in nutrition of higher animals, including humans (Hem, 1985, p. 146).
Silica (SiO₂)	Dissolved in most natural water in hydrated form [Si(OH) ₄] from rocks and soils containing minerals such as quartz, kaolinite, or potassium feldspar (Hem, 1985, p. 69-73).	Commonly 1 to 30 mg/L with concentrations up to 100 mg/L occurring frequently (Hem, 1985, p. 73).	No enforceable standard.	Silica solubility is controlled by temperature and pH, and changes in these properties may cause precipitation of silicate minerals from solution.
Dissolved solids	Sum of all minerals dissolved in water. Concentrations may be increased by industrial wastes, sewage, agricultural drainage, or naturally by evapotranspiration.	Ground water is generally in the range of 25 to 1,000 mg/L (Hem, 1985, p. 31).	Secondary standards: 500 mg/L unless alternate supply not available, then 1,000 mg/L (NBCHPS).	Specific effects upon water uses depend upon individual constituents present.

TABLE 1.--Background information on constituents and properties of water--Continued

Constituent or property	Source or cause of occurrence	Normal range of values in natural waters	Standards or criteria for water use ¹	Remarks
Principal Nutrients				
Nitrogen (N)	Derived from atmosphere by nitrogen fixation or leached from decaying organic matter, fertilizer, sewage, or industrial, agricultural, and domestic wastes. Nitrogen generally occurs in ground water as nitrate (NO_3^-), nitrite (NO_2^-), ammonium (NH_4^+), ammonia (NH_3), and organic nitrogen. Cyanide (CN^-) may also be introduced to ground water through improper waste disposal (Hem, 1985, p. 124-126).	Nitrate, less than 10 mg/L; nitrite, ammonium, ammonia, and organic nitrogen, all less than 1 mg/L (Hem, 1985, p. 124-126).	Primary standard: Nitrate, 10 mg/L as N or 44 mg/L as NO_3^- ; no enforceable standards for other nitrogen species (NBCHPS).	Nitrate concentrations in excess of 10 mg/L (as N) may cause methemoglobinemia (infant cyanosis, or "blue-baby" syndrome). Nitrogen is also an essential nutrient which may promote aquatic plant growth in lakes and streams. High concentrations of dissolved nitrogen may indicate contamination from agricultural, domestic, or industrial wastes, or from fertilizer.
Phosphorus (P), and ortho-phosphorus (PO_4^{3-})	Derived from phosphate minerals (notably apatite); common trace constituent of many rocks and soils. May be present in sewage and agricultural runoff.	--	No enforceable standard. Criterion for freshwater aquatic life: 0.025 to 0.05 mg/L as P (EPA, 1986).	Used as component of agricultural fertilizer and some detergents. Encourages growth of nuisance algae in lakes and streams where phosphorus is a limiting nutrient.
Minor Constituents				
Aluminum (Al)	Found in silicate rocks. Low- and high-pH waters may contain high concentrations (Hem, 1985, p. 73-75).	Generally 30 to 300 $\mu\text{g}/\text{L}$ (Hem, 1985, p. 73).	None.	Gastrointestinal irritation can occur from large oral doses. Aluminum is used as building material and in industry.
Antimony (Sb)	Derived mainly from the mineral stibnite (Hem, 1985, p. 145).	Concentrations can be expected to be very small in most natural waters; thermal waters may contain a few hundred micrograms per liter (Hem, 1985, p. 145).	Criteria: 146 $\mu\text{g}/\text{L}$ through ingestion of water and contaminated organisms (EPA, 1986).	Acute poisoning may result from ingestion of antimony. Used with lead alloys in storage batteries and in rubber and textile industries.

TABLE 1.--Background information on constituents and properties of water--Continued

Constituent or property	Source or cause of occurrence	Normal range of values in natural waters	Standards or criteria for water use ¹	Remarks
Argon (Ar)	Radioactive decay of Potassium-40 (Hem, 1985, p. 154).	Atmosphere contains about 1 percent argon. Concentrations in solution in ground water should reflect the concentrations in atmosphere (Hem, 1985, p. 154).	None.	Colorless and odorless. Used in gas-filled electric lamps.
Arsenic (As)	Associated with volcanic minerals and metallic ore deposits. Common in thermal ground water.	--	Primary standard: 50 µg/L (NBCHPS).	Trivalent arsenic (arsenite) is more toxic than pentavalent arsenic (arsenate). Epidemiologic studies by U.S. Public Health Service suggest that elevated concentrations in drinking water may be related to increased incidence of skin cancer (Hammond and Belliles, 1980, p. 437-438).
Barium (Ba)	Dissolved in small amounts from rocks and soils containing soluble barium salts. Higher concentrations have been reported associated with certain oilfield waters and other brines. Common minerals are barite and Witherite (Hem, 1985, p. 135-137).	Reported median concentration in public water supplies: 43 µg/L (Hem, 1985, p. 137).	Primary standard: 1,000 µg/L (NBCHPS).	Uses: metallurgy, paint, glass, electronics, and medicine. May affect the central nervous system and gastrointestinal system and may act as muscle stimulant, especially of heart muscle (EPA, 1986).
Beryllium (Be)	Rare element found in crustal rocks. Can be found in higher concentrations in acid water (Hem, 1985, p. 135).	Generally less than a few tenths of a microgram per liter in river water (Hem, 1985, p. 135).	None.	Coal combustion contributes beryllium to environment (Hammond and Belliles, 1980 p. 438).
Bismuth (Bi)	Byproduct of tin, lead, and copper ores.	Concentration in seawater is about 0.02 µg/L (NAS-NAE, 1973, p. 244).	None.	Used in heat-sensitive devices, silvering of mirrors, and in electronics industry. Chemical toxicity in humans consists of decreased appetite, foul breath, weakness (Hammond and Belliles, 1980, p. 439-440).

TABLE 1.--Background information on constituents and properties of water--Continued

Constituent or property	Source or cause of occurrence	Normal range of values in natural waters	Standards or criteria ¹ for water use ¹	Remarks
Boron (B)	Dissolved in small to moderate amounts from soils and rocks containing sodium or calcium borate salts. Higher concentrations have been associated with volcanic areas and geothermal spring water (Hem, 1985, p. 129).	Commonly a few tenths of a milligram per liter (Hem, 1985, p. 129).	Standard: 750 µg/L for long-term irrigation of sensitive crops (EPA, 1986). Uses: fire retardants, glass, leather tanning and finishing, cosmetics, photography, metallurgy, and high-energy rocket fuels. Essential element for plant growth, but sensitive crops have shown toxic effects at concentrations less than 1,000 µg/L. No evidence that it is required by animals (EPA, 1986).	Uses: fire retardants, glass, leather tanning and finishing, cosmetics, photography, metallurgy, and high-energy rocket fuels. Essential element for plant growth, but sensitive crops have shown toxic effects at concentrations less than 1,000 µg/L. No evidence that it is required by animals (EPA, 1986).
Cadmium (Cd)	Dissolved in small amounts from rocks and soils containing minerals such as sphalerite, commonly associated with zinc and copper ores. High concentrations may be found in landfill leachate (Hem 1985, p. 142).	Commonly less than 10 µg/L (Hem, 1985, p. 142).	Primary standard: 10 µg/L (NBCHPS). Criteria: 10 µg/L for irrigation water; for aquatic life, criterion is related to water-hardness concentration (EPA, 1986). Uses: electroplating, paint, printing inks, plastics, electrical batteries, and fluorescent and video tubes. Causes deterioration of bones in humans. Irrigation-water criteria established on basis of human toxicity and tendency to accumulate in plants. Acute toxicity to aquatic life is buffered by hardness and salinity.	Uses: electroplating, paint, printing inks, plastics, electrical batteries, and fluorescent and video tubes. Causes deterioration of bones in humans. Irrigation-water criteria established on basis of human toxicity and tendency to accumulate in plants. Acute toxicity to aquatic life is buffered by hardness and salinity.
Cesium (Cs)	Rare element found in nature as component of the mineral pollucite (Hammond and Bellies, 1980, p. 441).	Estimated average of 0.02 µg/L in river water (Hem, 1985, p. 134).	None.	Used as a catalyst in manufacture of photoelectric cells.

TABLE 1.--Background information on constituents and properties of water--Continued

Constituent or property	Source or cause of occurrence	Normal range of values in natural waters	Standards or criteria ¹ for water use ¹	Remarks
Chromium (Cr)	Dissolved in very small amounts from rocks and soils containing minerals such as chromite, and is found in greater relative abundance in magnesium- and iron-rich igneous rocks. High concentrations may indicate contamination from waste-disposal leachate. Ground water has been polluted in many places as a result of industrial applications (Hem, 1985, p. 138).	Commonly less than 10 $\mu\text{g/L}$ (Hem, 1985, p. 138).	Primary standard: 50 $\mu\text{g/L}$ (NBCHIPS).	Plating processes are the primary industrial application of chromium. Trivalent chromium is essential element in animal metabolism of glucose and lipids. Occupational exposure to hexavalent chromium compounds causes dermatitis, penetrating ulcers on hands and forearms, perforation of nasal septum, and inflammation of larynx and liver. Epidemiological studies estimate relative risk of chromate plant workers for respiratory cancer is 20 times greater than that of general population. Laboratory mice, given 5 mg/L hexavalent chromium in drinking water, had slightly higher incidence of malignant tumors than control mice (Hammond and Beliles, 1980, p. 441-442).
Cobalt (Co)	More common in ultrabasic igneous rocks (Rankama and Sahama, 1950, p. 684).	Generally waters have less than 1.0 $\mu\text{g/L}$ (Hem, 1985, p. 139).	None.	Increased levels of cobalt in water may cause goiter. Essential for plant and animal nutrition but in small amounts.
Copper (Cu)	Dissolved in small amounts from rocks and soils containing minerals such as chalcopyrite and chalcocite. Also leached from water pipes and plumbing fixtures by water with less than neutral pH (Hem, 1985, p. 141). High concentrations are associated with acid drainage from mines.	Commonly less than 10 $\mu\text{g/L}$ (Hem, 1985, p. 141).	Secondary standard: 1,000 $\mu\text{g/L}$. Criteria: 500 $\mu\text{g/L}$ for livestock water; 200 $\mu\text{g/L}$ for long-term irrigation (EPA, 1986).	Copper is essential to plant and animal metabolism, but range between deficiency and toxicity is low for organisms such as algae, fungi, some invertebrates, and fish, which lack effective barriers to control absorption. Monogastric mammals, including humans, are less sensitive to copper than ruminants, but excessive ingestion of copper salts may cause death (Hammond and Beliles, 1980, p. 443).
Gallium (Ga)	Byproduct of aluminum, copper, lead, and zinc ores.	--	None.	Used in high-temperature thermometers, arc lamps, alloys and seals for glass and vacuum equipment (Hammond and Beliles, 1980, p. 444).

TABLE 1.--Background information on constituents and properties of water--Continued

Constituent or property	Source or cause of occurrence	Normal range of values in natural waters	Standards or criteria for water use ¹	Remarks
Germanium (Ge)	Byproduct of some ores, including zinc.	--	None.	Used in electronics, fine lenses, some aluminum alloys, and as a catalyst (Hammond and Beilles, 1980, p. 44).
Iron (Fe)	Dissolved from iron-bearing minerals present in most rocks and soils. Found in some industrial wastes, and can be corroded from pipes, well casings, pumps, and other equipment. Also can be concentrated in wells and springs by certain bacteria.	Concentrations in ground water as high as 1,000 to 10,000 $\mu\text{g/L}$ may be common in some aquifers. Areal distribution is commonly erratic (Hem, 1985, p. 83).	Secondary standards: 300 $\mu\text{g/L}$ unless alternate supply is unavailable, then 600 $\mu\text{g/L}$ (NBCRPS).	Oxidizes to reddish-brown sediment. Stains utensils, enamelware, clothing, and plumbing fixtures. May cause taste and odor problems objectionable for food and beverage processing.
Lead (Pb)	Dissolved in small amounts from soils and rocks containing minerals such as galena (principal ore of lead). Lead minerals are most abundant in sedimentary rock. "Leaded" gasoline and lead water pipes also can increase concentrations of lead (Hem, 1985, p. 43-144).	Less than 10 $\mu\text{g/L}$ in potable water (Hem, 1985, p. 143-144).	Primary standard: 50 $\mu\text{g/L}$ (NBCHPS).	Uses: paints, batteries, and in sport-hunting and fishing industry. Lead adversely affects the central nervous system, peripheral nerves, kidney, and hematopoietic system. Chronic or sub-chronic exposure to high concentrations of inorganic lead may lead to commonly fatal condition referred to as lead encephalopathy, whereas toxic effects of icky lead compounds on central nervous system result in hallucinations, delusions, and excitement, progressing to delirium in fatal cases. Other effects of lead exposure include colic, chromosomal aberrations, and abnormal sperm morphology. Inhalation and ingestion are principal modes of exposure (Hammond and Beilles, 1980, p. 418-421).
Lithium (Li)	Found in pegmatite minerals and natural brines (Hem, 1985, p. 134).	Generally range from 1 to 3 $\mu\text{g/L}$ in dilute natural water (Hem, 1985, p. 134).	None.	Lithium is used in alloys and in medicine.

TABLE 1.--Background information on constituents and properties of water--Continued

Constituent or property	Source or cause of occurrence	Normal range of values in natural waters	Standards or criteria for water use ¹	Remarks
Manganese (Mn)	Dissolved from some rocks, soils, and lake-bottom sediments. Generally associated with iron; often associated with acid drainage from mines (Hem, 1985, p. 86).	Generally less than 1,000 $\mu\text{g/L}$; usually less than iron (Hem, 1985, p. 89).	Secondary standards: 50 $\mu\text{g/L}$ unless alternate supply is unavailable, then 100 $\mu\text{g/L}$ (NBCHPS).	Oxidizes to dark brown or black sediment. Poses problems similar to those of iron.
Mercury (Hg)	Dissolved in very small amounts from soils and rocks containing minerals such as cinnabar (principal ore of mercury).	Less than 1.0 $\mu\text{g/L}$ in potable water (Hem, 1985, p. 142-143).	Primary standard: 2 $\mu\text{g/L}$ (NBCHPS).	Use as amalgam for gold and silver extraction may have increased its abundance in vicinity of pre-1900 mining operations. Other uses: electrical, electrolytic preparation of chlorine and caustic soda, thermometers, pharmaceuticals, dentistry, and as agricultural and industrial biocide. Mercury is highly poisonous element that is known to accumulate in aquatic organisms. Also accumulates in organs of animals and humans. Adverse effects of mercury are principally manifested in kidney and central nervous system. Neurotoxicity of mercury poisoning occurs due to disruption of integrity of blood-brain barrier, inhibition of protein synthesis, and blocked synaptic and neuromuscular transmission. Mercury nephrotoxicity results only from exposure to inorganic mercury, and pathogenic mechanism is not well understood. Other effects include stomatitis, gingivitis, and inflammation of intestinal mucosa (Hammond and Bellies, 1980, p. 424-426).

TABLE 1. --Background information on constituents and properties of water--Continued

Constituent or property	Source or cause of occurrence	Normal range of values in natural waters	Standards or criteria for water use ¹	Remarks
Molybdenum (Mo)	Accessory element in many metal ores and fossil fuels (Hem, 1985, p. 140).	Generally less than 1 $\mu\text{g/L}$ in surface water unaffected by pollution. Concentrations near 4 $\mu\text{g/L}$ have been found in streams affected by molybdenum mining (Hem, 1985, p. 140).	No enforceable standard.	Used in steel alloys and in ceramics.
Nickel (Ni)	Found in crustal rocks (Hem, 1985, p. 139).	Uncontaminated natural waters should have a few micrograms per liter (Hem, 1985, p. 139).	Standard: 0.013 mg/L for drinking water (EPA, 1986).	Important industrial metal. Used in stainless steel.
Rubidium (Rb)	Byproduct of potassium and molybdenum production.	--	None.	Used in the manufacture of photovoltaic cells (Hammond and Bellies, 1980, p. 454).
Selenium (Se)	Dissolved in very small amounts from rocks and soils containing minerals such as Clausthalite, ferroelite, or Chalcomenite (Fairbridge, 1972, p. 1080). Also may be leached from soils containing detritus of selenium-accumulating vegetation (organic selenium) or selenium salts (for example, ferric selenite or calcium selenate (Wickett and Alfors, 1986, p. 105)).	Rarely exceeds 1 $\mu\text{g/L}$ in potable water. Up to 3,000 $\mu\text{g/L}$ in drainage water from seleniumiferous irrigated soils (Hem, 1985, p. 145-146).	Primary standard: 10 $\mu\text{g/L}$ (NBCHPS).	Selenium is essential nutrient for animals, and its deficiency in livestock diet is common. However, when intake becomes excessive, selenium toxicity can result--"blind staggers" in livestock and embryonic deformities in waterfowl.

TABLE 1.--Background information on constituents and properties of water--Continued

Constituent or property	Source or cause of occurrence	Normal range of values in natural waters	Standards or criteria for water use ¹	Remarks
Silver (Ag)	Dissolved in small amounts from rocks and soils containing minerals such as argentite or cerargyrite (Fairbridge, 1972, p. 1032). Limited solubility and distribution of silver suggests its occurrence in ground water may indicate contamination from silver mining/milling operations or improper disposal of photographic-processing wastes (Hem, 1985, p. 141).	Much less than 10 $\mu\text{g/L}$ in most natural water (Hem, 1985, p. 141).	Primary standard: 50 $\mu\text{g/L}$ (NBCHPS).	Uses: jewelry and coinage, photography, and electronics; silver iodide has been used in "cloud seeding" to induce or intensify precipitation (Hem, 1985, p. 141). Elemental silver is not considered toxic (although it does cause skin discoloration: argria), but most silver salts are toxic due to associated anions.
Strontium (Sr)	Fairly common element in igneous-rock minerals (Hem, 1985, p. 135).	Median content for larger U.S. public water supplies, 0.11 mg/L. Concentrations above 1 mg/L have been found in some U.S. ground waters (Hem, 1985, p. 135).	None.	Used in small amounts in lead and tin alloys.
Tin (Sn)	Derived mainly from the ore cassiterite.	--	None.	Used in manufacture of tinplate, food packaging, and solder. Ingested orally, tin or its inorganic compounds require relatively large doses to produce toxicity (Hammond and Bellies, 1980, p. 458).
Titanium (Ti)	Abundant in crustal rocks.	Generally present in amounts ranging up to a few tens of micrograms per liter (Hem, 1985, p. 137).	None.	Used in the aircraft and space industry.
Vanadium (V)	Present in fossil fuels and volcanic rocks (Hem, 1985, p. 135).	Ground and surface waters rarely have more than 10 $\mu\text{g/L}$ (Hem, 1985, p. 138).	None.	A byproduct of petroleum refinement. Found in many foods.

TABLE 1.--Background information on constituents and properties of water--Continued

Constituent or property	Source or cause of occurrence	Normal range of values in natural waters	Standards or criteria for water use ¹	Remarks
Zinc (Zn)	Dissolved in small amounts from rocks or soils containing minerals such as sphalerite, willemite, or zinc-rich magnetite (Fairbridge, 1972, p. 1293).	Less than 100 $\mu\text{g/L}$ in potable water (Hem, 1985, p. 142).	Secondary standard: 5,000 $\mu\text{g/L}$ (NBCHPS).	Uses: metallurgy, paint, rubber, and paper products. Zinc is considered essential element to plant and animal life, but water is not normally a significant dietary source. Human dwarfism and lack of sexual development have been related to zinc deficiency. Consumption of acidic food or beverages from galvanized containers has caused accidental poisoning, with symptoms such as fever, vomiting, stomach cramps, and diarrhea (Hammond and Bellles, 1980, p. 460-462).
Zirconium (Zr)	Found in mineral zircon.	--	None.	Used in the nuclear industry, metal alloys, catalysts, dyes, pigments on ceramics, abrasives, and cigarette-lighter flints (Hammond and Bellles, 1980, p. 462).
Alpha, gross	Measure of total radioactivity due to alpha-particle emission, as inferred from measurements on a dry sample (EPA, 1976, p. 28404).	--	15 pCi/L, exclusive of radon and uranium, but including radium-226 (EPA, 1976, p. 28404).	Used for screening purposes as gross measure of compliance regarding maximum contaminant levels for radionuclides.
Beta, gross (as Cs-137)	See gross beta (as Sr-90/Y-90)	--	15 pCi/L, exclusive of radon and uranium, but including radium-226 (EPA, 1976, p. 28404).	Used for screening purposes as gross measure of compliance regarding maximum contaminant levels for radionuclides.
Beta, gross (as Sr-90/Y-90)	Measure of total radioactivity due to beta-particle emission, as inferred from measurements on a dry sample (EPA, 1976, p. 28404).	--	Primary standard: 4 mrem per year (EPA, 1976, p. 28404).	See gross alpha .

TABLE 1.--Background information on constituents and properties of water--Continued

Constituent or property	Source or cause of occurrence	Normal range of values in natural waters	Standards or criteria for water use ¹	Remarks
Radium-226 (²²⁶ Ra)	Dissolved in very small amounts from rocks and soils containing minerals such as uranite or carnotite in which uranium-238 has been replaced by radium-226 through natural radioactive decay. Radium-226 (half-life: 1,620 years) is lost from solution by continued radioactive decay to daughter-product, radon-222 gas (Hem, 1985, p. 148-149).	Recent EPA survey of 59,812 public water-supply systems nationwide resulted in a range for radium-226 from less than 1 pCi/L to more than 40 pCi/L. Approximately 1 percent (less than 500 supplies) exceeded 5 pCi/L (Cothern and Lappenburg, 1984, p. 503).	Primary standard, radium-226 plus radium-228 combined: 5 pCi/L (NBCHPS).	Human health effects have been investigated extensively concerning individuals involved in luminous-dial industry (radium-dial Painters) and individuals who received radium as therapeutic nostrum during early 1900's. Because radium is metabolic analog of calcium, it is deposited in skeleton, where it serves as source of alpha radiation to bone and contiguous tissue (Hobbs and McClellan, 1980, p. 529).
Tritium (³ H)	Produced naturally in outer atmosphere and by humans in nuclear reactions (Hem, 1985, p. 150).	20,000 pCi/L, which is average annual concentration assumed to produce a total-body or organ dose of 4 mrem per year (EPA, 1976, p. 28404).	None.	Tritium, incorporated into water molecules, is readily absorbed into bloodstream from gastrointestinal tract, skin, and lungs, and is distributed as body water (Hobbs and McClellan, 1980, p. 522).
Uranium (U)	Dissolved in small amounts from rocks and soils containing minerals such as uranite or carnotite (pitchblende) (Fairbridge, 1972, p. 1216). Uranium-238 is predominant isotope of natural uranium and is starting point in radioactive-decay series that includes radium-226 and radon-222 and ends with stable lead-206 isotope (Hem, 1985, p. 148).	Generally less than 10 µg/L in most natural water (Hem, 1985, p. 148).	No enforceable standard. Concentration greater than or equal to 0.5 mg/L constitutes hazard in marine environment (NAS-NAE, 1973, p. 257).	Natural uranium (predominantly uranium-238 plus small amounts of uranium-235 and uranium-234) commonly is not a drinking-water health concern due to its low solubility. Soluble forms are reported to exhibit toxicity to kidneys through chemical action rather than radiation (Hobbs and McClellan, 1980, p. 521).

TABLE 1.--Background information on constituents and properties of water--Continued

Constituent or property	Source or cause of occurrence	Normal range of values in natural waters	Standards or criteria ¹ for water use	Remarks
<i>Organic Constituents</i>				
Dissolved organic carbon (DOC)	Dissolved in moderate amounts from land-surface organic matter and from fossilized organic matter, kerogen (Thurman, 1985, p. 14-15)	From 0.2 to 15 mg/L; commonly less than 2 mg/L (Thurman, 1985, p. 8-9).	No enforceable standard.	Normal concentrations of dissolved organic carbon play significant role in aqueous geochemistry and can facilitate the movement of charged molecules and ions through an aquifer. High concentrations may indicate contamination from landfill leachate.
NAS (methylene blue active substances)	Detergents.	Generally less than 0.1 mg/L (NAS-NAE, 1973, p. 190).	0.5 mg/L (NAS-NAE, 1973, p. 67).	Can be component of sewage and septic-tank effluent.
Methane	Natural gas; is product of anaerobic bacterial processes.	Odor threshold is 200 mg/L (Weiss, 1986, p. 665).	None.	Colorless gas. High concentrations may cause asphyxiation (Weiss, 1986, p. 665).
Ethane	Natural gas.	Odor threshold is about 900 mg/L (Weiss, 1986, p. 459).	None.	Same as for methane.

¹ Primary drinking-water standards specify maximum contaminant levels that are health related and federally mandated; secondary drinking-water standards are based on esthetic qualities and are enforceable by the State of Nevada (Jeffrey A. Fontaine, Nevada Bureau of Consumer Health Protection Services, oral communication, 1989). Criteria are recommended limits for specific water uses, based on current scientific knowledge. Some standards and criteria for trace elements and organic compounds that are expressed in milligrams per liter in the cited references are herein converted to micrograms per liter to maintain consistency with units of measure used in the accompanying water-quality data tabulations.

FIGURE 3.--Sites where primary drinking-water standard for fluoride (4.0 mg/L) has been exceeded. Total sites, 110.

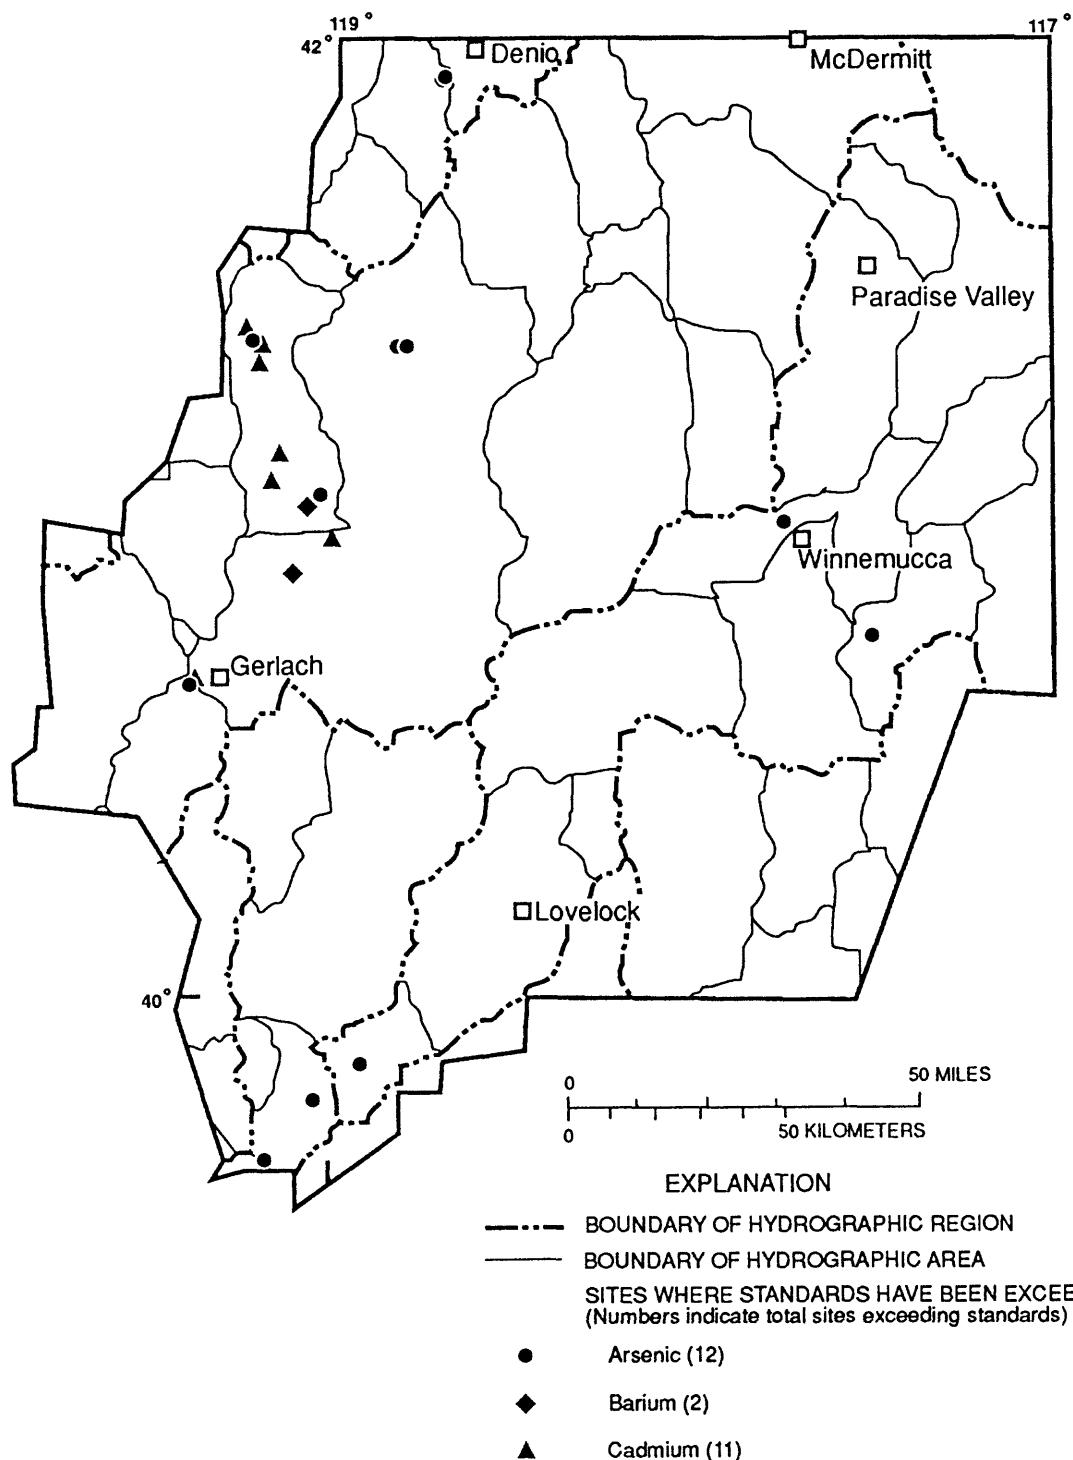

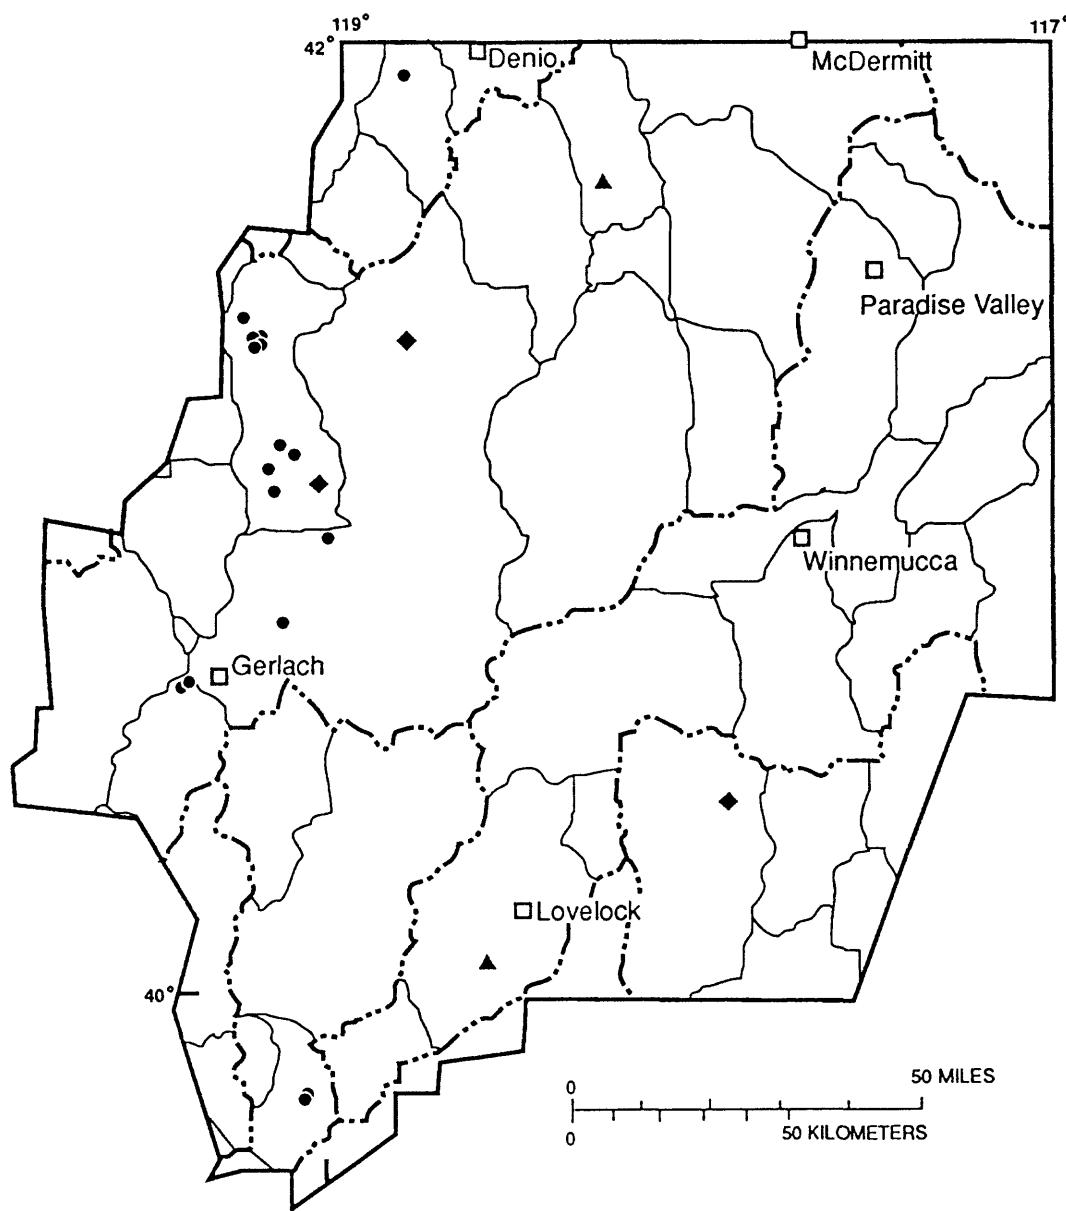

FIGURE 4.--Sites where primary drinking-water standards for arsenic (50 µg/L), barium (1,000 µg/L), and cadmium (10 µg/L) have been exceeded.

- EXPLANATION**
- - - BOUNDARY OF HYDROGRAPHIC REGION
 - — — BOUNDARY OF HYDROGRAPHIC AREA
 - SITES WHERE STANDARDS HAVE BEEN EXCEEDED
(Numbers indicate total sites exceeding standards)
 - Lead (23)
 - ◆ Mercury (3)
 - ▲ Nitrate (2)

FIGURE 5.--Sites where primary drinking-water standards have been exceeded for lead (50 µg/L), mercury (2 µg/L), and nitrate (44 mg/L as NO₃).

TABLE 3.--Recommended criteria for dissolved constituents and properties of water used for agriculture

[From National Academy of Sciences and National Academy of Engineering, (1973, p. 298-366) unless otherwise noted. Abbreviations: Type of use.--I, irrigation; L, livestock. Units of measure.-- $\mu\text{S}/\text{cm}$, microsiemens per centimeter at 25 °Celsius; mg/L, milligrams per liter. Symbols: <, less than; >, greater than; \leq , less than or equal to.]

Constituent	Use	Criteria for use		
pH	L	No limit, but waters with pH less than 4.5 can affect the toxicity of other constituents.		
	I	4.5-9.0 pH units with care taken to look at possible harmful secondary effects.		
Dissolved solids	L	Upper limit 5,000 mg/L stated by some investigators; for best growth of animals should be considerably below the upper limit (Hem, 1985, p. 213).		
	I	< 500 mg/L, no detrimental effects; 500-1,000 mg/L, can have detrimental effects to sensitive crops; 1,000-2,000 mg/L, can have detrimental effects on many crops; 2,000-5,000 mg/L, water can be used for tolerant crops on permeable soils with careful management practices.		
Sodium-adsorption ratio (SAR) and sodium hazard	L	No recommendation.		
	I	Four categories of sodium hazard (low, medium, high, and very high) are defined by decreasing SAR values with increasing specific-conductance values. Ranges of SAR in each hazard category, for specific conductances of 100 and 5,000 $\mu\text{S}/\text{cm}$ are:		
		Sodium hazard	SAR range for 100 $\mu\text{S}/\text{cm}$	SAR range for 5,000 $\mu\text{S}/\text{cm}$
		Low	0-10	0-2.5
		Medium	10-18	2.5-6.5
		High	18-26	6.5-11
		Very high	>26	>11
(U.S. Salinity Laboratory Staff, 1954, p. 80).				
Sulfide	L	No recommendation (unpleasant taste and odor would prevent usage).		
	I	No recommendation.		
Fluoride	L	2.0 mg/L.		
	I	1.0 mg/L for continuous use on all soils; 15 mg/L for use on neutral and alkaline, fine-textured soils for 20 years.		
Nitrite as N	L	\leq 10 mg/L, to provide a margin of safety.		
	I	No recommendation.		
Nitrate as NO_3^-	L	400 mg/L.		
	I	No recommendation.		
Aluminum	L	5.0 mg/L.		
	I	5.0 mg/L for continuous use on all soils; 20 mg/L for use on fine-textured, neutral to alkaline soils for 20 years.		
Arsenic	L	0.20 mg/L.		
	I	0.10 mg/L for continuous use on all soils; 2.0 mg/L for use on fine-textured, neutral to alkaline soils for up to 20 years.		
Beryllium	L	No recommendation.		
	I	0.10 mg/L for continuous use on all soils; 0.50 mg/L for use on neutral to alkaline, fine-textured soils for 20 years.		

TABLE 3.--Recommended criteria for dissolved constituents and properties of water used for agriculture--Continued

Constituent	Use	Criteria for use
Boron	L I	5.0 mg/L. 0.75 mg/L for long-term irrigation of sensitive crops (U.S. Environmental Protection Agency, 1986).
Cadmium	L I	0.05 mg/L. 0.01 mg/L for continuous use on all soils; 0.05 mg/L for use on neutral and alkaline, fine-textured soils for 20 years.
Chromium	L I	1.0 mg/L. 0.10 mg/L for continuous use on all soils; 1.0 mg/L for use on neutral and alkaline, fine-textured soils for 20 years.
Cobalt	L I	1.0 mg/L. 0.05 mg/L for continuous use on all soils; 5.0 mg/L for use on neutral and alkaline, fine-textured soils for 20 years.
Copper	L I	0.50 mg/L. 0.20 mg/L for continuous use on all soils; 5.0 mg/L for use on neutral and alkaline, fine-textured soils for 20 years.
Iron	L I	No recommendation. 5.0 mg/L for continuous use on all soils; 20 mg/L for use on neutral to alkaline soils for 20 years.
Lead	L I	0.10 mg/L. 5.0 mg/L for continuous use on all soils; 10 mg/L for use on neutral and alkaline, fine-textured soils for 20 years.
Lithium	L I	No recommendation. 2.5 mg/L for continuous use on all soils except for citrus, where 0.075 mg/L is recommended.
Manganese	L I	No recommendation. 0.20 mg/L for continuous use on all soils; 10 mg/L for use on neutral and alkaline, fine-textured soils for up to 20 years.
Mercury	L I	0.01 mg/L. No recommendation.
Molybdenum	L I	Upper limit has not been set. 0.01 mg/L for continuous use on all soils; 0.05 mg/L for short-term use on soils that react with this element.
Nickel	L I	No recommendation. 0.20 mg/L for continuous use on all soils; 2.0 mg/L for use on neutral, fine-textured soils for up to 20 years.
Selenium	L I	0.05 mg/L. 0.02 mg/L for continuous use on all soils.
Vanadium	L I	0.10 mg/L. 0.10 mg/L for continuous use on all soils; 1.0 mg/L for use on neutral and alkaline, fine-textured soils for 20 years.
Zinc	L I	25 mg/L. 2.0 mg/L for continuous use on all soils; 10 mg/L for use on neutral and alkaline soils for 20 years; on fine-textured, calcareous and organic soils, the concentrations can exceed the limit by a factor of 2 or 3 with little toxicity for 20 years.

TABLE 4.--Relative tolerance of selected plants to boron
(modified from Eaton, 1935)

[In each group, the plants first named are considered more sensitive, and the last named more tolerant]

Sensitive	Semitolerant	Tolerant
Lemon	Lima bean	Carrot
Grapefruit	Sweet potato	Lettuce
Avocado	Bell pepper	Cabbage
Orange	Pumpkin	Turnip
Thornless blackberry	Zinnia	Onion
Apricot	Oat	Broadbean
Peach	Milo	Alfalfa
Cherry	Corn	Garden beet
Apple	Wheat	Sugar beet
Pear	Barley	
Plum	Field pea	
American elm	Raddish	
Pecan	Sweet pea (flower)	
	Tomato	
	Pima cotton	
	Acala cotton	
	Potato	
	Sunflower	

Aquatic Life

Irrigated farm land can affect the habitat of aquatic life (plant and animal organisms) because runoff and subsurface drainage water from agricultural fields may have higher concentrations of dissolved constituents than the water initially applied to the fields. Irrigation runoff and subsurface drainage water sometimes flow directly into wildlife areas by way of drains (such as those in the Stillwater Wildlife Management Area) and affect the habitat of aquatic life.

Water from wells is seldom used for aquatic habitat, but many springs in the Winnemucca District support aquatic life. If ground water is used to supplement streamflow, aquatic life could also be affected. Physical and chemical changes in an aquatic habitat can alter the behavior of aquatic organisms either directly or through secondary organisms.

The USGS data base used as a source of water-quality data for this study contains no information on potentially toxic constituents such as pesticides, and has limited data for detergents and most dissolved gases. However, data for other constituents that affect aquatic life, such as alkalinity, pH, dissolved solids, and trace constituents, are included. Table 5 lists criteria for selected constituents and properties of water used for aquatic life.

Water temperature can drastically affect growth of fish and other aquatic life. However, water temperature is not included in table 5 because different species have varying tolerances. Information about how water temperature affects aquatic life is discussed by the U.S. Environmental Protection Agency (1986).

Recreational Use

Ground water generally is not used for recreation, except where springs provide inflow to streams and where geothermal springs are used for swimming; thus, the water quality of springs can be important.

Swimming in geothermal springs generally does not appreciably increase the deep body temperature in humans (National Academy of Sciences and National Academy of Engineering, 1973, p. 32). Whole-body immersion (swimming or bathing) in water about 40 °F or lower generally is more harmful than swimming in water about 100 °F. However, the harm to an individual varies with the temperature of the water, duration of exposure, and metabolic rate of the individual (National Academy of Sciences and National Academy of Engineering, p. 33).

The recommended range for pH of water used for immersion of the human body is from 6.5 to 8.3. The lacrimal fluid (tears) in the eye has a pH of about 7.4 and a relatively high buffering capacity (National Academy of Sciences and National Academy of Engineering, 1973, p. 33), thus the pH of water for swimming should range from about 6.5 to 8.3 to prevent eye irritation.

The recommended chemical characteristics of water used for whole-body immersion ensure that the water is nontoxic to the skin and mucous membranes (National Academy of Sciences and National Academy of Engineering, 1973, p. 30). In addition, water used for whole-body immersion should not contain chemicals that, if ingested in small quantities, would be toxic to humans.

TABLE 5.--Recommended criteria for aquatic life for selected constituents and properties of water used for aquatic habitat

[Abbreviations and symbols: mg/L, milligrams per liter; µg/L, micrograms per liter; EPA, U.S. Environmental Protection Agency (1986); NAS-NAE, National Academy of Sciences and National Academy of Engineering (1973, p. 130-193); <, less than; ≤, less than or equal to]

Constituent or characteristic	Criteria for use
Color	Increased color (in combination with turbidity) should not reduce the depth of the compensation point for photosynthetic activity by more than 10 percent from the seasonally established norm for aquatic life (EPA).
Hardness	Effects of hardness on freshwater fish and other aquatic life appears to be related to the ions causing the hardness (EPA).
pH	6.5 to 9.0 pH units is considered adequate for freshwater aquatic life. In addition, a water should not have a large fluctuation in daily or seasonal pH values (EPA).
Alkalinity	A minimum concentration has been set at 20 mg/L unless a lower concentration occurs naturally (EPA).
Ammonia	Ammonia (NH_3), not the ammonium ion (NH_4^+), has been demonstrated to be the principal toxic form. For additional information see EPA.
Sulfide	0.002 mg/L to protect aquatic organisms within the general limits of pH and water temperature, for total sulfides (NAS-NAE).
Dissolved solids	An excess of dissolved solids may destroy habitat-forming plants. Lakes with 15,000 mg/L are considered unsuitable for most freshwater fishes (EPA).
Nitrite	≤5 mg/L should protect most warm-water fish; <0.06 mg/L should protect salmonoid fish (EPA).
Nitrate	Concentrations of nitrate that would exhibit toxic effects on warm- or cold-water fish could rarely occur in nature, thus restrictive criteria are not recommended (EPA).
Phosphorus	Total phosphorus criteria to control aquatic growth is not presented. Total phosphates as phosphorus should not exceed 0.05 mg/L in any stream where it enters a lake or reservoir, nor 0.025 mg/L within the lake or reservoir, to prevent development of biological nuisances and to control accelerated eutrophication (EPA).
Aluminum	Where ionic aluminum is suspected, careful examination of toxicity problems should be made (NAS-NAE).
Antimony	Acute toxicity to freshwater aquatic life occurs at 9.0 mg/L (EPA).
Arsenic	Varies between biological species and oxidation state because chemistry of arsenic in water is complex (EPA).
Barium	A restrictive criterion for aquatic life appears unwarranted (EPA).
Beryllium	Acute toxicity occurs at concentrations as low as 130 µg/L (EPA).
Boron	Naturally occurring concentrations should have no effect on aquatic life (EPA).

TABLE 5.--Recommended criteria for aquatic life for selected constituents and properties of water used for aquatic habitat--Continued

Constituent or characteristic	Criteria for use
Cadmium	0.03 mg/L where total hardness as calcium carbonate is greater than 100 mg/L; 0.004 mg/L where total hardness as calcium carbonate is less than 100 mg/L (NAS-NAE).
Chromium	Mixed aquatic populations should be protected where concentration of total chromium in water does not exceed 0.05 mg/L at any one time or place (NAS-NAE).
Copper	21 and 34 $\mu\text{g}/\text{L}$ (EPA). Criterion calculated according to formula published by EPA, which incorporates an ambient hardness value. These values are based on a hardness value of 200 mg/L as calcium carbonate. Freshwater aquatic organisms should not be adversely affected if the 4-day average concentration (first value) is not exceeded more than once every 3 years on the average and if the 1-hour average concentration (second value) is not exceeded more than once every 3 years on the average.
Iron	1.0 mg/L (EPA).
Lead	0.03 mg/L (NAS-NAE).
Manganese	Not considered to be a problem in freshwater (EPA).
Mercury	0.0002 mg/L in unfiltered water (NAS-NAE).
Nickel	283 and 2,550 $\mu\text{g}/\text{L}$ (EPA). Criterion calculated according to formula published by EPA, which incorporates an ambient hardness value. These values are based on a hardness value of 200 mg/L as calcium carbonate. Freshwater aquatic organisms should not be adversely affected if the 4-day average concentration (first value) is not exceeded more than once every 3 years on the average and if the 1-hour average concentration (second value) is not exceeded more than once every 3 years on the average.
Selenium	Concentration of total recoverable selenite should not exceed 260 $\mu\text{g}/\text{L}$ at any time. Acute toxicity to freshwater aquatic life occurs for inorganic selenate at concentrations of 760 $\mu\text{g}/\text{L}$ and would occur at lower concentrations for more sensitive species (EPA).
Silver	13 $\mu\text{g}/\text{L}$ (EPA). Criterion calculated according to formula published by EPA, which incorporates an ambient hardness value. These values are based on a hardness value of 200 mg/L as calcium carbonate.
Zinc	190 and 210 $\mu\text{g}/\text{L}$ (EPA). Criterion calculated according to formula published by EPA, which incorporates an ambient hardness value. These values are based on a hardness value of 200 mg/L as calcium carbonate. Freshwater aquatic organisms should not be adversely affected if the 4-day average concentration (first value) is not exceeded more than once every 3 years on the average and if the 1-hour average concentration (second value) is not exceeded more than once every 3 years on the average.

WATER-QUALITY DATA

This report presents data compiled from published reports, limited NBCHPS analyses, and the USGS water-quality data base. Principal constituents and properties, and the more commonly analyzed trace constituents, are listed in table 6, part A. Part B includes additional data for ions, other trace constituents, gases, radionuclides, and organics. Concentrations of trace constituents in Part B are expressed in micrograms per liter. To convert micrograms per liter to milligrams per liter, multiply by 0.001. The 530 wells and springs for which data on ground-water quality are available are shown on plate 1.

A brief statistical summary of constituents that had more than five determinations is presented in table 7. Values with remarks ("less than" values) were used in the calculations; thus, for some constituents the statistics may be skewed higher than the true population statistics.

Stable isotope data were available for some sites (114). The stable isotopes listed in table 8 are carbon-13 relative to carbon-12, deuterium (hydrogen-2) relative to hydrogen-1, and oxygen-18 relative to oxygen-16. Each ratio is determined for a sampled water, and is then compared to a standard. The standard for oxygen-18 and deuterium is the international reference standard known as Vienna Standard Mean Ocean Water (V-SMOW) and for carbon-13 is the Pee Dee Belemnite (PDB). By convention, the computed results are expressed as "delta carbon-13," "delta deuterium," and "delta oxygen-18"; the units of measure are parts per thousand (abbreviated "permil"). A negative delta value indicates that the sampled water is isotopically lighter than the standard (that is, the sampled water has a smaller proportion of oxygen-18, deuterium, or carbon-13, relative to oxygen-16, hydrogen-1, or carbon-12 than the standard).

¹ Each data-collection site has been assigned both a unique short "Map number" and a standard USGS site identification number. The short map numbers range from 2 to 534 and are shown on plate 1. (Data for sites 1, 26, 35, and 103 were originally included in this study but later eliminated because those sites were found to be slightly outside the study area.) The standard identification number consists of 15 digits and represents geographic location. The first six digits denote the degrees, minutes, and seconds of latitude; the next seven digits denote the degrees, minutes, and seconds of longitude; and the last two digits (assigned sequentially) identify the sites within a 1-second grid. For example, site 393923119170601 refers to 39°39'23" latitude and 119°17'06" longitude, and it is the first site recorded in that 1-second grid. That assigned number is retained as a permanent identifier even if a more precise latitude and longitude are later determined.

TABLE 7.--Maximum, minimum, and median values for selected constituents and properties of water from wells and springs

[Abbreviations and symbols: BL, below reporting limit for analytical procedure used; E, estimated; FET, fixed endpoint titration; fld, field; IT, incremental titration; lab, laboratory; mg/L, milligrams per liter; °C, degrees Celsius; µg/L, micrograms per liter; µS/cm, microsiemens per centimeter at 25 °C; <, less than; --, not determined]

Number of determinations	Constituent	Maximum	Minimum	Median
249	Specific conductance, field ($\mu\text{S}/\text{cm}$)	47,700	155	810
190	pH, field (standard units)	11.7	4.7	8.0
499	Water temperature ($^{\circ}\text{C}$)	116.5	8.0	20
21	Color (platinum cobalt units)	40	2	3
21	Turbidity (Jackson turbidity units)	7	BL	1

21	Magnesium, total (mg/L as Mg)	100	1	11
394	Magnesium, dissolved (mg/L as Mg)	480	BL	4.2
14	Sodium, total (mg/L as Na)	1,500	9	21
383	Sodium, dissolved (mg/L as Na)	31,000	10	150
342	Sodium-adsorption ratio	4,000	.3	11
124	Sodium + potassium, dissolved (mg/L as Na)	E6,400	E13	62.5
14	Potassium, total (mg/L as K)	130	1	2
378	Potassium, dissolved (mg/L as K)	230	BL	9.7
93	Bicarbonate, whole water, FET, fld (mg/L as HCO_3)	1,210	3	200
116	Bicarbonate, IT, fld (mg/L as HCO_3)	9,560	2	231
75	Carbonate, whole water, FET, fld (mg/L as CO_3)	86	BL	BL
110	Carbonate, IT, fld (mg/L as CO_3)	902	BL	2
117	Alkalinity, whole water, FET (mg/L as CaCO_3)	992	2	144
39	Sulfide, dissolved (mg/L as S)	2.1	BL	BL
21	Sulfate, total (mg/L as SO_4)	200	4	56
493	Sulfate, dissolved (mg/L as SO_4)	4,500	3	59
541	Chloride, dissolved (mg/L as Cl)	44,000	4	48
20	Fluoride, total (mg/L as F)	4.8	.1	.2
311	Fluoride, dissolved (mg/L as F)	16	BL	1.8
29	Bromide, dissolved (mg/L as Br)	8	BL	.2
16	Iodide, dissolved (mg/L as I)	.4	BL	.01
345	Silica, dissolved (mg/L as SiO_2)	280	.8	61
67	Solids, residue at 180 °C, dissolved (mg/L)	16,500	186	532
28	Residue at 105 °C, dissolved (mg/L)	17,000	85	525
363	Solids, sum of constituents, dissolved (mg/L)	84,200	122	573
36	Nitrogen nitrate, dissolved (mg/L as N)	1.5	BL	.105
20	Nitrogen nitrate, total (mg/L as NO_3)	220	BL	1.4
135	Nitrogen nitrate, dissolved (mg/L as NO_3)	63	BL	.8

TABLE 7.--Maximum, minimum, and median values for selected constituents and properties of water from wells and springs--Continued

Number of determinations	Constituent	Maximum	Minimum	Median
14	Nitrogen nitrite, dissolved (mg/L as N)	0.05	BL	0.01
12	Nitrogen nitrite + nitrate, dissolved (mg/L as N)	.94	.01	.105
13	Nitrogen ammonia, total (mg/L as N)	.80	.10	.40
8	Nitrogen ammonia, dissolved (mg/L as N)	1.0	BL	.45
19	Phosphorus, total (mg/L as PO ₄)	.22	.02	.04
11	Phosphorus, dissolved (mg/L as PO ₄)	2.0	<.10	.10
39	Aluminum, dissolved (μg/L as Al)	520	BL	10
28	Antimony, dissolved (μg/L as Sb)	300	3	30
18	Arsenic, total (ug/L as As)	110	BL	5
56	Arsenic, dissolved (μg/L as As)	160	BL	12
89	Barium, dissolved (μg/L as Ba)	2,900	3	100
75	Beryllium, dissolved (μg/L as Be)	20	<.5	1
5	Bismuth, dissolved (μg/L as Bi)	<100	<100	<100
299	Boron, dissolved (μg/L as B)	16,000	BL	500
76	Cadmium, dissolved (μg/L as Cd)	61	<1	3
25	Cesium, dissolved (μg/L as Cs)	4,800	<70	150
14	Chromium, dissolved (μg/L as Cr)	--	<1	20
65	Cobalt, dissolved (μg/L as Co)	3	<3	<3
91	Copper, dissolved (μg/L as Cu)	230	BL	11
66	Iron, total (μg/L as Fe)	2,400	BL	20
123	Iron, dissolved (μg/L as Fe)	32,000	BL	23
21	Iron (μg/L as Fe)	730	BL	50
77	Lead, dissolved (μg/L as Pb)	510	BL	28
165	Lithium, dissolved (μg/L as Li)	5,300	4	220
132	Manganese, dissolved (mg/L as Mn)	1,000	BL	19.5
13	Manganese (μg/L as Mn)	160	BL	10
100	Mercury, dissolved (μg/L as Hg)	4	BL	.2
70	Molybdenum, dissolved (μg/L as Mo)	240	<10	20.5
15	Nickel, dissolved (μg/L as Ni)	60	<1	20
25	Rubidium, dissolved (μg/L as Rb)	1,700	<20	120
15	Selenium, dissolved (μg/L as Se)	--	<1	<50
15	Silver, dissolved (μg/L as Ag)	--	<1	<20
99	Strontium, dissolved (μg/L as Sr)	17,000	BL	400
13	Tin, dissolved (μg/L as Sn)	--	20	100
8	Titanium, dissolved (μg/L as Ti)	--	<2	<500
70	Vanadium, dissolved (μg/L as V)	85	<3	6
89	Zinc, dissolved (μg/L as Zn)	1,500	BL	18
